Abstract

We attempted to solve the Movie-Chain-Runner Problem, a computational problem equivalent to the well-known Longest Path Problem. We designed and used Python to implement several algorithms for the problem, and include our best solution. In the end, we accomplished our original goal of constructing a movie chain of at least 300 titles. We also performed some analyses of both the problem and our algorithms, and use them here to discuss approaches to the problem. Finally, we overview and reflect on our group's approach and success.

1 Introduction

We first introduce the Movie-Chain-Runner Problem, our solution, and our success.

1.1 The Movie-Chain-Runner Problem

The Movie-Chain-Runner Problem is to find the longest chain of overlapping titles in a list of movie titles, where two titles are said to overlap if some suffix of the first movie is identical to some prefix of the second movie. For example, in the list

- Day of the Dead
- Live and Let Die
- Dead Poets' Society
- Die Another Day
- The Last Samurai

the longest chain consists of 4 titles:

Live and Let Die Another Day of the Dead Poets' Society

Our project is to approximately solve the Movie-Chain-Runner Problem for a given list of 6561 movie titles. By appropriately representing the movie list as a graph, we found that the Movie-Chain-Runner Problem is equivalent to the Longest Path Problem (finding the longest simple path in a directed graph). The Longest Path Problem is well known to be NP-Hard, meaning that no efficient algorithm exists to find longest paths in large graphs, including our movie graph. A review of the literature reveals that good approximate longest paths also cannot be found efficiently in large graphs.¹ Thus, our project is to study the movie title graph and innovate ways to find long paths in the graph.

1.2 Solution

We constructed our longest chain in four major steps. Our first step was to reconstruct the list of movie titles as a directed graph, thus reducing the problem to the well-known Longest Path Problem. The second step was to implement a simple brute-force algorithm. The final two steps involved augmenting this brute-force algorithm with two new procedures: “reversal” and “replacement.” The algorithms are described in detail under Section 2.3. on page 2.

1.3 Did We Succeed?

Our original goal was to surpass 300 titles. Despite some early setbacks leading us to lower our goal to 285 titles, we reached our original goal of 300 titles with a chain of 301 titles and 961 words (see Appendix B for the full movie chain). We did not achieve the optional goal of 328 titles needed to set a new record.

¹Björklund, Husfeldt, Khanna, “Approximating longest directed paths and cycles,” ICALP, 2004. (accessed June 26, 2013 a <http://citeseerx.ist.psu.edu/viewdoc/similar?doi=10.1.1.105.262>).

2 Approach

2.1 Programming Languages

Our team considered programming in Python, C, or MATLAB. We settled on Python because our entire team was familiar with Python, whereas only some team members had used C or MATLAB. Although C and MATLAB are faster languages, they are harder to use, and it would have taken too much time for team members to learn either. Jimmy also wrote Bash scripts to run our algorithms in parallel on cluster machines.

2.2 Algorithms

We present several algorithms (both successful and unsuccessful) that we considered.

Algorithms that worked:

Our first attempt at a solution was a brute-force algorithm which greedily followed every path in a depth-first search pattern, and retained the longest path found. We ran this algorithm until it ceased to make appreciable progress at a chain of 243 titles.

Our next step, “reversal,” was to reverse all edges in the movie graph and use the brute force algorithm to extend the beginning of the 243 title chain. We felt this approach would be useful because, upon running our original algorithm multiple times, we found that the beginning of the chain changed significantly, but end of the chain was always the same, suggesting that the end of the chain was already nearly optimal. Again, we ran the algorithm until it ceased to make appreciable progress, this time with a chain of 277 titles.

Our final step, “insertion,” checked if there was a longer subchain between two titles in our 277 title chain. Simply attempting to “squeeze” chains in between titles in our chain only increased our chain length to 278. However, when we allowed the insertion algorithm to replace entire subchains (“replacement”), we were able to construct our longest chain of 301 titles before the algorithm ceased to make much progress.

Algorithms that didn’t work:

We tried an algorithm that computes acyclic subgraphs of our graph and then runs a polynomial time Longest Path algorithm known for acyclic graphs. However, the number of cycles proved too large to generate all the subgraphs, and so we abandoned this effort.

We also considered some more elaborate algorithms we found in the literature: a color-coding algorithm proposed by Alon et al.² and the genetic algorithms studied by Portugal et al.³ However, due to the complexity of implementing these algorithms and the success of our simpler algorithms, we opted not to try them.

2.3 Schedule

Figure 1 below shows the original Gantt chart presented in our project proposal. Figure 2 below shows the revised Gantt chart we presented in our progress report. The only changes were that the 300 title goal originally set for June 25 was eliminated and the 285 title goal originally set for June 17 was extended to June 25. In practice, the only deviation from our original schedule was achieving our 285 title goal one day late (June 18), but we caught up by reaching our 300 title goal the next day (June 19).

3 Results

We succeeded in finding a movie chain of 301 titles, fulfilling our scheduled goal of having a 300+ title chain by June 25.

Algorithm	Longest Chain
Brute-Force	243
Brute-Force w/ reversal	277
Brute-Force w/ reversal and insertion	278
Brute-Force w/ reversal and replacement	301

Table 1: Longest chain found by each algorithm

4 Discussion

Here we present the project evaluation promised in our proposal, followed by a discussion of lessons learned from the project and the resulting recommendations for future groups.

4.1 Evaluation

As suggested in our proposal, we evaluated the success of our project using three methods.

Method 1: Longest Chain Length

Our project was a success in that the number of titles in our longest chain exceeded 300. Although we failed to establish a new record, this secondary goal was optional and not expected.

Method 2: Algorithm Comparison

Our second method of evaluation was to compare different algorithms to decide on a “best” algorithm for the problem. Although we did not test a diverse selection of algorithms, we did try several variants on the basic brute force algorithm (as explained on page 2, under Section 2.3. Table 1 above presents the longest chain found by each variant. It is clear from the results that both reversal and replacement are important augmentations of the basic brute-force algorithm.

Method 3: Time Prediction

In order to gauge the difficulty of the problem at hand, we also attempted to predict the time needed to solve the problem by exploring all possible paths in the movie graph. To do this, we first measured the time taken to solve the problem on many random subgraphs of the movie graph and used this data to fit an exponential relation between the size of the graph and the time taken for the computation. We then extrapolated this relation to conclude that performing the computation on the entire graph would take about 1.03 trillion years, approximately 100 times the lifespan of the sun. Appendix A gives a detailed discussion of the experiment and its results and validity.

4.2 Lessons Learned

We learned several things about programming for large computational problems:

- Using primarily brute-force algorithms, we came quite close to (likely within 13% of) the optimal solution. Thus, although far from optimal in theory, brute-force algorithms can produce decent solutions for some NP-hard problems in practice.

- For algorithms with large asymptotic runtimes, constant factors are important - a 50% runtime reduction is very significant when the algorithm can take a day or more to run. This fact is really understated in CS classes.
- With a high level language (like Python) it is crucial to consider all available data structures and their implementations. We noticed too late that using a set rather than a list for part of our code might have sped up our program by a factor of 100.

4.3 Recommendations

Based on our experience, we strongly recommend attempting to implement simple algorithms first when tackling an NP-hard problem. While much of the literature is focused on optimizing asymptotic performance, in practice, a well implemented brute-force algorithm may perform nearly optimally with the time and hardware available, while being much simpler to implement correctly. Consequently, we also recommend trying to fully optimize code for such an implementation fairly early, since much time can be wasted in running the original program when one will later run a significantly optimized version.

Our team's work ethic and organization were crucial to our success. We recommend having frequent meetings (at least twice weekly) in order to coordinate work and ensure team members remain engaged.

Appendices

A Time Prediction

To gauge the difficulty of the problem at hand, we predicted the time needed to solve the problem by exploring all possible paths in the movie graph. For $k \in \{100, 200, \dots, 2500\}$, we first generated 100 random subgraphs, each induced by k titles chosen uniformly at random. We then measured the runtime on each subgraph, and averaged over samples to estimate the runtime for k titles. We fitted an exponential relation between the size of the graph and the runtime (the parameters of the exponential are included in Figure 3). Evaluating this exponential function at $x = 6561$ gives an estimate of **1.03 trillion years** needed to compute the solution for the entire 6561 title movie graph.

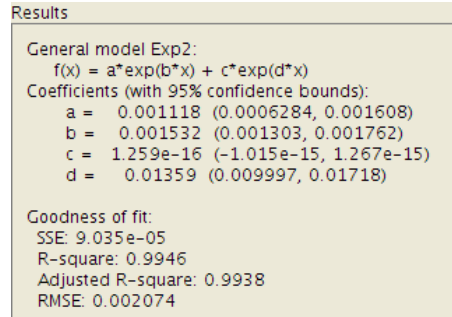

Figure 3: Exponential function from graph size to runtime

Figure 4 shows the fitted plot of how the runtime scales with the size of movie graph.

Figure 4: Plot of runtime (in seconds) over graph size (in titles).

The high R^2 value suggests that our data fit the exponential relation quite well. Since we measured runtime rather than operations performed, the results depend on our programming language and computer. The tests were run sequentially in Python on a single GHC cluster machine. However, a powerful computer running C would reduce the runtime by at most a factor of 10,000, and so the computation would still take millions of years.

B Our Longest Movie Chain

Here, we include our current longest movie chain, with 301 titles and 961 words:

THE GOSPEL	FEAR STRIKES OUT
THE GOSPEL OF JOHN	OUT OF THE PAST
JOHN Q	PAST MIDNIGHT
Q AND A	MIDNIGHT RUN
A PERFECT MURDER	RUN SILENT RUN DEEP
MURDER AND MURDER	DEEP BLUE
MURDER IN THE FIRST	DEEP BLUE SEA
